

**Supplementary material**

Appendix I. Model selection results of the multistate models describing resighting, survival and transition probabilities of black-tailed godwits.

In the first selection step of the mark-resighting multistate model, the step for resighting probability, two models were within 2  $\Delta$ AICc, however one model had only one extra parameter without lowering the AICc and was therefore not competitive (Arnold 2010). Consequently, the best model showed only an effect of age and markings on resighting probability (Table A1a). In the next selection step, in which apparent survival was modelled, two models were within 2  $\Delta$ AICc. The best supported model showed, in addition to the predicted grassland type effect, a year-dependent survival on chicks ringed in the nest. The second best supported model did not show this year-dependent effect for chicks ringed in the nest. Both models showed an effect of grassland type on survival of the chicks ringed at an older age and a time-dependent survival for adults, but adult survival was not affected by grassland type (Table A1b). At the last step, in which transitions between grassland types were modelled, two models were within 2  $\Delta$ AICc. Both models included an age and grassland type dependent transition probability (Table A1c).

Table AIa. Model selection of the first step, resighting probability structure, of the multistate mark-recapture models of black-tailed godwits breeding on meadows and monocultures. The model structure for apparent survival and transition probability were kept with fullest parameterization. The two models shown in bold are within 2  $\Delta$ AICc and were used for the second step, modelling apparent survival structure.

Model notations: a2 is two age classes, ring is effect of marking (engraved codeflag or colour ring combination), hab is effect of grassland type, time is year effect. Additional effects are notated with + and interaction effects with  $\times$ . Notations before the slash are for birds in their second year and after the slash for birds older than two years old.

Table A1b. Model selection in the second step, apparent survival structure, of the multistate mark-recapture models of black-tailed godwits breeding on meadows and monocultures. The model structure for transition probability were kept with fullest parameterization. The four models shown in bold are within 2  $\Delta$ AICc and were used for the second step, modelling apparent survival structure.
